

# Imperialist competition algorithm for distributed generation connections

A. Soroudi M. Ehsan

Center of Excellence in Power System Management and Control, Department of Electrical Engineering, Sharif University of Technology, Tehran, Iran

E-mail: alireza.soroudi@gmail.com

**Abstract:** This study proposes an imperialist competition algorithm (ICA) to maximise the benefits of distribution network operators (DNOs) because of the existence of distributed generation (DG) units. The sum of active loss reduction and network investment deferral incentives has been considered as the objective function to be maximised in this study. The optimal location and size of DG units in the network are found considering various techno-economical issues. The application of the proposed methodology in the UK under current Ofgem financial incentives for DNOs is investigated. The ability of the proposed approach in finding the optimal solution is validated by comparing the obtained results with other methods of the literature.

## Nomenclature

### Indices

$i, j$	bus
$\ell$	feeder

### Constants

$\gamma$	network investment deferral incentive
$\psi$	active loss reduction incentive

### Variables

$P_i^D$	active power demand in bus $i$
$P_i^{dg}$	active power injected by a dg in bus $i$
$Y_{ij}$	admittance magnitude between bus $i$ and $j$
$\theta_{ij}$	admittance angle between bus $i$ and $j$
$S_i^{dg}$	apparent power of dg installed in bus $i$
$P_{i,base}^D$	base active power demand in bus $i$
$Q_{i,base}^D$	base reactive power demand in bus $i$
$S_{i,base}^D$	base apparent power demand in bus $i$
$I_\ell$	current magnitude of $\ell$ th feeder
$CP_c$	power of $c$ th colony
$IP_i$	power of $i$ th imperialist
$EP_i$	power of $i$ th empire
$V_{min}$	lower operation limit of voltage
$\bar{P}_{lim}^{dg}$	maximum operating limit of a dg

$P_i^{net}$	net active power injected to bus $i$
$Q_i^{net}$	net reactive power injected to bus $i$
$N_b$	number of buses in the network
$N_c$	number of colonies
$N_{E_i}$	number of colonies in $i$ th empire
$\cos\varphi^{dg}$	power factor of a dg
$Q_i^{dg}$	reactive power injected by a dg in bus $i$
$Q_i^D$	reactive power demand in bus $i$
$\bar{I}_\ell$	capacity limit of existing feeder $\ell$
$V_{max}$	upper operation limit of voltage
$V_i$	voltage magnitude in bus $i$
$\delta_i$	voltage angle in bus $i$

## 1 Introduction

### 1.1 Motivation

The role of distributed generation (DG) units has become much more important with the deregulation of power industry. These units are interesting options for distribution network operators (DNOs) to meet the requirements of their customers. The main point of deregulation is to split generation, transport and consumption of electrical energy between independent parties. Therefore DG units installed nowadays are not owned by DNOs. DNOs typically only give permission for connection of DG units to distribution network (i.e. check whether DG unit satisfies technical requirements). Although in unbundled environment the DNO does not decide about the location and size of DG units and he is faced with different types of uncertainties [1], these quantities have direct impact on DNO's benefits.

The DG planning problem (finding the optimal size and location) is a mixed integer non-linear problem (MINLP). Generally finding the global optimal solution of a MINLP problem is a difficult task. Therefore the DNO needs a computation tool to deal with this problem. This paper presents a new methodology to answer this need.

### 1.2 Literature review

The DG units change the flow of energy over the feeders of the distribution network by injecting active and reactive power to their interconnection node. The DG units may bring different benefits for DNOs such as: shorter construction period [2], network investment deferral [3], active loss reduction [4–6], environmental emission reduction [7] and reliability improvement [8, 9]. The benefits of DG units highly depend on the size and location of them in the network. Many methods have been proposed in the literature to find the optimal location and size of DG units in the network which have considered various technical aspects such as: voltage limits, feeder capacity limits and penetration level. Additionally, there are some regulatory issues that may change the potential benefits of DG units for DNOs. These frameworks are widely classified into two categories: DG owned and unbundled DNO [10]. In DG-owned DNO category, the DNO is allowed to perform DG investment. This gives DNO the opportunity to make decision about the size and location of DG units. The second category prohibits the DNO of DG ownership/investment. The DG units are installed and operated by DG owners. The main goal of DG operator/owners is maximising its benefits. This can be used by DNO to identify the optimal location and size of DG units as a guide for DG investors and steer their decisions. The DG-owned category has been highly investigated in the literature [3, 7, 11]. Few literature deal with unbundled DNO [12–14]. In [12], a Kalman filter algorithm is proposed to find the optimal size of DG units to reduce active losses. In [13], a hybrid GA-OPF is proposed to find the size and location of a predefined number of DG units to increase the incentives received by DNO because of network reinforcement deferral and loss reduction. The genetic algorithm (GA) finds the connections nodes and the OPF finds the optimal size of DG units. In [14], an ordinal optimisation approach is proposed for reducing the search space of the problem in [13], which shows improvement in the results.

### 1.3 Contribution

A heuristic method named imperialist competition algorithm (ICA) is proposed to find the optimal size and location of DG units to maximise the benefits of DNO. The proposed algorithm is robust and computationally efficient in comparison with previously proposed methods of the literature.

### 1.4 Paper organisation

This paper is set out as follows: Section 2 presents problem formulation, Section 3 sets out the proposed solution method for solving the problem. The application of the proposed model and the simulation results are presented in Section 4, and finally, the conclusion is drawn in Section 5.

## 2 Problem formulation

The DG sizing and placement is done for a predefined number of DG units, that is,  $N_{dg}$ . The decision variables are the binary

decision variable, that is,  $\xi_i^{dg}$ , which shows the installation of a DG unit in bus  $i$  and also the capacity of installed DG, that is,  $S_i^{dg}$ , in bus  $i$ . The constraints and the objective function are explained next.

### 2.1 Constraints

**2.1.1 Power flow constraints:** The power flow equations to be satisfied for each sizing and placement scheme are as follows

$$\begin{aligned} P_i^{net} &= -P_i^D + \sum_{dg} P_i^{dg} \\ Q_i^{net} &= -Q_i^D + \sum_{dg} Q_i^{dg} \\ P_i^{net} &= V_i \sum_{j=1}^{N_b} Y_{ij} V_j \cos(\delta_i - \delta_j - \theta_{ij}) \\ Q_i^{net} &= V_i \sum_{j=1}^{N_b} Y_{ij} V_j \sin(\delta_i - \delta_j - \theta_{ij}) \end{aligned} \quad (1)$$

**2.1.2 Operating limits of DG units:** The DG units should be operated considering the limits of their primary resources, that is

$$P_i^{dg} \leq \bar{P}_{lim}^{dg} \quad (2)$$

The power factor of DG unit is kept constant, as follows

$$\cos \varphi^{dg} = \text{const} \quad (3)$$

**2.1.3 Voltage profile:** The voltage magnitude of each bus should be kept between the operation limits, as follows

$$V_{min} \leq V_i \leq V_{max} \quad (4)$$

**2.1.4 Capacity limit of feeders:** To maintain the security of the feeders, the flow of current passing through them should be kept below their capacity limit, as follows

$$I_\ell \leq \bar{I}_\ell \quad (5)$$

where  $I_\ell$  is the current passing through feeder  $\ell$  and  $\bar{I}_\ell$  is the capacity limit of feeder  $\ell$ .

**2.1.5 Number of installed DG units:** It is tried to find the optimal size and location of a predefined number of DG units in a given network. The total number of all installed DG units should be equal to a given number, that is,  $N_{dg}$ , as follows

$$\sum_{i=1}^{N_b} \xi_i^{dg} = N_{dg} \quad (6)$$

### 2.2 Objective function

The proposed model maximises the total benefits of DNO which is the sum of two incentives, namely, total incentive

of network reinforcement deferral and total loss reduction incentive, as follows

$$\begin{aligned} & \max\{OF\} \\ & \text{subject to:} \\ & (1) \rightarrow (6) \end{aligned}$$

The values of incentives because of network reinforcement deferral and total loss reduction are formulated next.

**2.2.1 Total incentive for active loss reduction:** Different schemes exist for considering the effect of loss reduction on the benefits of DNO. One of the appropriate models is calculating the difference between total loss of the system before and after DG placement [10, 11, 13, 15]. In some models [11], the DNO should pay/receive equal to the electricity price multiplied by amount of loss reduction/increase and in some models [10, 13, 15] a fix incentive, that is,  $\psi$ , is paid to DNO for each MWh reduction of active losses. This paper uses the second model as follows

$$\mu_l = \psi \times \left( \text{Loss}^{no\,dg} - \sum_{i=1}^{N_b} P_{i,t}^{net} \right) \quad (7)$$

where  $\text{Loss}^{no\,dg}$  is the active loss when no DG unit is installed in the network.

**2.2.2 Total incentive for network reinforcement deferral:** The network investment deferral effect of DG units is one of the important technical and economical

Fig. 2 Single-line diagram of the 69-bus distribution network

values of DG units for DNO. This effect is even known as ‘non-wire solution’ [16, 17], to meet the load growth. One method for exact calculation of this deferral is integrated planning models [18] in which network reinforcement and DG planning are performed simultaneously. The other methods use simplifying assumptions by assuming that each MVA of installed DG reduces the need for reinforcing substation and feeders [13, 15]. In this model, the incentive because of investment deferral in network is proportional to the total installed DG in the network, as follows

$$\mu_n = \gamma \times \sum_{i=1}^{N_b} P_i^{dg} \quad (8)$$

where  $\gamma$  is the coefficient of incentive for each MW of installed DG units.

The objective function is calculated as follows

$$OF = \mu_l + \mu_n \quad (9)$$

The DG placement problem defined here is an MINLP. The heuristic search methods have been successful in solving such problems. An ICA is proposed for solving the defined problem in the next section.

Table 1 Data used in the study

Parameter	Unit	Value
$N_{imp}$	–	10
$W_1$	–	0.8
$W_2$	–	0.2
$V_{max}$	Pu	1.06
$V_{min}$	Pu	0.94
maximum iteration	–	200

### 3 Proposed imperialist competition algorithm

The ICA was first proposed in [18]. It is inspired by the imperialistic competition. It starts with an initial population called colonies. The colonies are then categorised into two groups, namely, imperialists (best solutions) and colonies (rest of the solutions). The imperialists try to absorb more colonies to their empire. The colonies will change according to the policies of imperialists. The colonies may take the place of their imperialist if they become stronger than it (propose a better solution). This algorithm has been successfully applied to PSS design [19] and data clustering [20]. The flowchart of the proposed algorithm is depicted in Fig. 1. The steps of the proposed ICA are described as follows:

*Step 1.* Generate an initial set of colonies with a size of  $N_c$ .

*Step 2.* Set iteration = 1.

*Step 3.* Calculate the objective function for each colony using (9) and set the power of each colony as follows

$$CP_c = OF \quad (10)$$

This means the less the OF is, the more stronger the  $IP_i$  is.

*Step 4.* Keep the best  $N_{imp}$  colonies as the imperialists and set the power of each imperialist as follows

$$IP_i = OF \quad (11)$$

*Step 5.* Assign the colonies to each imperialist according to the calculated  $IP_i$ . This means the number of colonies owned by each imperialist ( $(IP_i / \sum_{j=1}^{N_{imp}} IP_j) \times (N_c - N_{imp})$ ) is proportional to its power, that is,  $IP_i$ .

*Step 6.* Move the colonies towards their relevant imperialist using crossover and mutation operators.

*Step 7.* Exchange the position of a colony and the imperialist if it is stronger ( $CP_c > IP_i$ ).

Step 8. Compute the empire's power, that is,  $EP_i$  for all empires as follows

$$EP_i = \frac{1}{N_{E_i}} \times \left( w_1 \times IP_i + w_2 \times \sum_{c \in E_i} CP_c \right) \quad (12)$$

where  $w_1$  and  $w_2$  are weighting factors that are adaptively selected.

Step 9. Pick the weakest colony and give it to one of the best empires (select the destination empire probabilistically based on its power,  $EP_i$ ).

Step 10. Eliminate the empire that has no colony.

Step 11. If more than one empire remained then go to Step 6

Step 12. End.

## 4 Simulation results

The proposed ICA methodology is programmed in MATLAB running on an Intel® Core™2 Duo Processor T5300 (1.73 GHz) PC with 1 GB RAM. It is applied on a distribution system to demonstrate its abilities. The distribution network under study is a 11-kV, 69-bus system as depicted in Fig. 2.

The technical data of this network can be found in [13]. All DG units are assumed to operate with constant power factor equal to 0.9 lag. The loss reduction incentive, that is,  $\psi$ , and network deferral incentive, that is,  $\gamma$ , are highly dependent on the system under study but here for comparing the proposed method with the other published results, these are assumed to be 48 (£/MWh) and 2.5

[£/kW/(year)] [13–15], respectively. The thermal capacity of lines, that is,  $\bar{I}_\ell$ , are assumed to be 3 MVA. The other simulation parameters are provided in Table 1.

The active loss of the network is 0.228 MW when no DG units exists in the network, that is,  $loss^{no\,dg}$ . The simulations are done for different number of DG units (three, five, seven and nine) and the results obtained by the proposed ICA method.

### 4.1 Determination of parameters for ICA

In this section the influence of ICA parameters on average total incentives is investigated (after 100 trials). The following procedure has been adopted to calculate optimum value of the mutation and crossover probabilities. Different colony sizes, that is,  $N_c$ , tried were 50, 80, 100, 150 and 200. For each colony size the crossover and mutation probabilities are increased from 0.1 to 0.9 in steps of 0.1 as described in Table 2. The performance of the proposed ICA is evaluated for all the above-mentioned combinations. Hundred independent trials have been made with 200 iterations per trial. The performance of the ICA also depends on the number of colonies. In Table 2 the performance of the ICA is checked also for different number of colonies. The parameters of ICA are selected based on the average total incentives obtained for different values of parameters given in Table 2. This total incentive is more than the previously reported best result of 11.588 £/h [21]. After a number of careful experimentation, following optimum values of ICA parameters have finally

**Table 7** Computational performance comparison between the proposed ICA and other methods for 100 trials

# of DG	Method	Average, £h <sup>-1</sup>	Standard deviation, £h <sup>-1</sup>	Worst solution, £h <sup>-1</sup>	Best solution, £h <sup>-1</sup>	Running time, s

	ICA	11.50	0.25	10.72	11.67	8742

been settled:  $N_c = 100$ ; crossover probability = 0.6, mutation probability = 0.2.

#### 4.2 Comparing with other methods

The result obtained by the proposed ICA method is compared with those of other methods: For classical method, the model is solved in generalised algebraic modelling systems (GAMS) [22], which is a high-level programming platform, using DIScrete COntinuous OPTimisation (DICOPT) solver. The evolutionary methods include ordinal optimisation (OO) [14], GA-OPF [13], particle swarm optimisation (PSO) [23], pure GA [24], immune algorithm [25] and immune genetic algorithm (IGA) [21]. The optimal sizing and placement schemes of each method are given in Tables 3–6, for different number of DG units. Execution time complexity of each optimisation method is very important for its application to real systems. The execution time of the proposed ICA is compared with other methods in Table 7. This table presents a comparison among the results of the proposed algorithm ICA and other methods for 100 random trials. In Table 7, the best and the worst solutions of the maximised objective function (total incentives) are also given. Comparison of the best and worst solutions of the proposed optimisation algorithm (ICA) with those of the other methods confirms the effectiveness of the proposed method. Additionally, Table 7 provides the standard deviation and average value of the objective function, based on the proposed method and the other ones. This would show the convergence characteristics of the proposed ICA compared with other methods.

The average value of objective function in the proposed ICA method is greater than other analysed methods whereas it has lower standard deviation. This means that the ICA is more robust compared to other heuristic methods such as GA-OPF, OO, PSO, GA, Immune and Immune-GA. The ICA uses the features of GA (mutation and crossover) to avoid trapping into a local optimum. Finally, the running time of the proposed ICA method, given in the last column of Table 7, is less than GA-OPF, GA, PSO, Immune, IGA. The best solution of ICA is also better than the the solution found by GAMS/DICOPT (classical method). This is because of the inherent mixed integer non-linear nature of the problem which makes it hard for classical methods to find the global optimum for a given solution. The classical methods are very sensitive to the initial starting points assigned to the variables specially in MINLP problems. The main drawback of the proposed method is that there is no proof for finding the global optimum solution in a given MINLP. This problem also exists in classical methods because they are very sensitive to the starting point of the decision variables (initial values). Another drawback lies in the computational burden and running time that would inevitably increase for a larger distribution system (like other heuristic algorithms). It was already demonstrated in Table 7 that the running time of ICA is more than GAMS method. It should be noted that although this computation is off-line and will not be a serious problem for the planner, it can be reduced by using fast distribution load flow techniques [26] proposed in the literature.

## 5 Conclusion

This paper proposes an ICA for optimal placement of DG units. The defined objective function is the total incentives received by DNO because of active loss reduction and network investment deferral. The proposed optimisation method is applied to a

distribution network to demonstrate its flexibility and effectiveness. The simulation results show that the ICA possesses better convergence characteristics and robustness compared to other heuristic methods. It is also clear from the results of different trials that implementing the ICA gives the solutions with higher quality, computational efficiency compared to other methods. The proposed method is not only useful when the DNO performs the DG placement and sizing but also when other non-DNO entities perform DG investment. In such cases, the DNO can even share the benefits with DG developers to reach into a win-win strategy.
